

Apps Script Coding Examples

Coding Examples Apps Script

Google Apps Script is a scripting platform that lets you extend Google Workspace by adding custom functionality to your Google Sheets, Docs, Forms, and Gmail. Google Apps Script is a cloud-based scripting language that provides easy ways to automate tasks across Google products and third-party services.

Top Tips for Google Apps Script	2
Converting a Google Document to plain text	4
Google Sheets add numbers from columns	6
Sheet Data and Cell Values	7
Add Image to Sheet Cell	9
New CellImage in Sheets	11

Logging to the console	12
Adding numbers and showing an alert	14
Read Data from from Sheet	16
Get sheet data - apply changes and set value in sheet data	18
Send email from Sheet	19
Use Sheet data for custom emails out	20
Send Emails to recipients from Sheet data	22
Send emails from User list in Sheets	23
Sending an email to all users from the spreadsheet data	25
Apps Script on Sheets examples	26
Using Sheet data create a chart update styling	29
Apps Script Create Calendar entries from Sheet data	31
Sheet data to create Calendar events	35
Calendar Events into Sheet	36
Sheet data to populate Calendar	37
Logs Email Attachments details	39
Get Gmail Attachments Log into Sheet	41
Create folder in drive from Sheet Data	43
Get attachments from Gmail and Copy To Drive	45

Top Tips for Google Apps Script

10 tips to help you improve your Google Apps Script coding:

1. Use the Google Apps Script Debugger: Google Apps Script has a built-in debugger that can help you find and fix errors in your code.
2. Test your code with sample data: Before you run your code on real data, test it with a small set of sample data to make sure it works as expected.
3. Use proper naming conventions: Naming your variables and functions in a consistent and descriptive manner will make your code easier to read and understand.
4. Comment your code: Adding comments to your code will help you (and others) understand what your code is doing, especially if it's complex.
5. Use arrays and objects effectively: Arrays and objects are powerful data structures in Google Apps Script. Learn how to use them effectively to simplify your code and make it more readable.
6. Use built-in functions and methods: Google Apps Script has many built-in functions and methods that you can use to perform common tasks. Take advantage of these to save time and make your code more efficient.
7. Avoid hardcoding values: Avoid hardcoding values in your code, such as cell references or URLs, as this can make your code difficult to maintain. Instead, use variables and functions to make your code more flexible.

8. Use error handling: Use error handling techniques to handle unexpected errors and keep your code running smoothly.
9. Write modular code: Write modular code by breaking your code into small, reusable functions that can be used in multiple places.
10. Keep your code organized: Keeping your code organized by using proper indentation, separating code into different functions and sections, and using meaningful variable names will make it easier to read, understand, and maintain.

Converting a Google Document to plain text

<https://youtu.be/csnsdM3NuJk>

Converting a Google Document to plain text:

```
function convertToPlainText() {  
  // Get the active document  
  const document = DocumentApp.getActiveDocument();  
  
  // Get the body of the document  
  const body = document.getBody();  
  
  // Get the plain text representation of the document  
  const plainText = body.getText();  
}
```

```
// Log the plain text to the console
Logger.log(plainText);
}
```

In this example, the `convertToPlainText()` function uses the `DocumentApp` class to convert a Google Document to plain text. The `DocumentApp.getActiveDocument()` method is used to get the active document, and the `document.getBody()` method is used to get the body of the document. The `body.getText()` method is then used to get the plain text representation of the document, which is logged to the console using the `Logger.log()` method.

Send the text version of the Doc using Apps Script to the email address of the apps script account

```
function converterText(){
  const doc = DocumentApp.openById(ID);
  const body = doc.getBody(); //DocumentBodySection
  const txt = body.getText();
  const email = Session.getActiveUser().getEmail();
  //Logger.log(email);
  MailApp.sendEmail(email,'My Doc Text',txt);
}
```

Google Sheets add numbers from columns

<https://youtu.be/O5PgoPCmcQU>

Google Apps Script that adds two numbers and displays the result in a Google Sheets cell:

```
function sumTwoNumbers() {  
    var sheet = SpreadsheetApp.getActiveSheet();  
    var cell1 = sheet.getRange("A1").getValue();  
    var cell2 = sheet.getRange("B1").getValue();  
    var result = cell1 + cell2;  
    sheet.getRange("C1").setValue(result);  
}
```

Explanation:

`function sumTwoNumbers()`: This is the declaration of the function `sumTwoNumbers`, which contains the code that will be executed.

`var sheet = SpreadsheetApp.getActiveSheet();`: This line creates a variable `sheet` and assigns the active sheet to it using the `SpreadsheetApp.getActiveSheet()` method.

`var cell1 = sheet.getRange("A1").getValue();` This line creates a variable `cell1` and assigns the value of cell A1 to it using the `getValue()` method.

`var cell2 = sheet.getRange("B1").getValue();` This line creates a variable `cell2` and assigns the value of cell B1 to it using the `getValue()` method.

`var result = cell1 + cell2;` This line creates a variable `result` and assigns the sum of `cell1` and `cell2` to it.

`sheet.getRange("C1").setValue(result);` This line sets the value of cell C1 to the value of `result` using the `setValue()` method.

To run this script, you would need to open a Google Sheet and then open the Apps Script editor by clicking on the "Tools" menu and selecting "Script editor." Then, paste the code into the editor, save the script, and run the `sumTwoNumbers()` function.

Sheet Data and Cell Values

<https://youtu.be/lakZoOLDFfs>

Adding numbers together, creating random numbers to populate the sheet data.

	A	B	C	D	E	F	G	H	I
1	67	19	105	191	3234	3616	1	7233	14466
2	23	99	133	255		953		510953	512416
3	80	51	229	360		720		720720	722160
4	42	62	163	267		433968		534433968	534868470
5	19	45	154	218		436		436436	437308
6	16	80	142	238		476		476476	477428
7	41	85	156	282		564		564564	565692
8	0	37	115	152		304		304304	304912
9	74	82	200	356		712		712712	714136
10	40	81	177	298		596		596596	597788

```
const ID = '132trk8qIk';
```

```
function adder(){
  const sheet =
  SpreadsheetApp.openById(ID).getSheetByName('add');
  const data = sheet.getDataRange().getValues();
  data.forEach((row,index) =>{
    let total = 0;
    row.forEach(cell => {
      if(cell){
        total = total + parseInt(cell);
      }
    })
    const rowValue = index+1;
    const range =
    sheet.getRange(rowValue,row.length+1,1,1);
    range.setValue(total);
  })
}
```

```
}
```

```
function makeNums(){  
  const ss = SpreadsheetApp.openById(ID);  
  const sheet = ss.getSheetByName('add');  
  for(let i=0;i<20;i++){  
    const arr = [getRan(),getRan(),getRan()];  
    sheet.appendRow(arr);  
  }  
  Logger.log(sheet);  
}
```

```
function getRan(){  
  return Math.floor(Math.random()*100);  
}
```

Add Image to Sheet Cell

<https://youtu.be/cbfxoPjqvhs>

add an image to a cell in a Google Sheets spreadsheet using Google Apps Script:

```
function addImageToCell() {  
    var sheet = SpreadsheetApp.getActiveSheet();  
    var imageUrl = "https://www.example.com/image.png";  
    var img = UrlFetchApp.fetch(imageUrl).getBlob();  
  
    sheet.insertImage(img, 1,1);  
}
```

Explanation:

First, we get a reference to the active sheet using `SpreadsheetApp.getActiveSheet()`.

Next, we get a reference to the cell where we want to insert the image using `sheet.getRange("A1")`. You can specify any cell you want by changing the argument to `getRange()`.

Then, we specify the URL of the image we want to insert using the `imageUrl` variable.

We use the `UrlFetchApp.fetch()` method to retrieve the image data from the specified URL. This method returns a `Response` object, which we get the binary data (the image) from using `getBlob()`.

Finally, we use the `sheet.insertImage()` method to insert the image into the specified cell. The first argument is the image data (the blob we obtained in step 4), and the second argument is the cell reference.

```
function imageAdder(){
  const ss = SpreadsheetApp.openById(ID);
  const sheet = ss.getSheetByName('my');
  const imageURL =
'http://www.discoveryvip.com/img/d.png';
  const img = UrlFetchApp.fetch(imageURL).getBlob();
  sheet.insertImage(img,20,20);
  Logger.log(img);
}
```

New CellImage in Sheets

To add an image into a specific cell this can be done using the `newCellImage` method.

```
function imageAdderCell(){
  const ss = SpreadsheetApp.openById(ID);
  const sheet = ss.getSheetByName('my');
```

```
    const range = sheet.getRange(1,1,3,3);
    const imageURL =
'http://www.discoveryvip.com/img/d.png';
    const image = SpreadsheetApp
    .newCellImage()
    .setSourceUrl(imageURL)
    .setAltTextTitle('discoveryvip')
    .build();
    range.setValue(image);
}
```

Logging to the console

<https://youtu.be/mxCnyr5Ov7w>

basic syntax and structure of a Google Apps Script.

```
function helloWorld() {
  // This line logs "Hello, world!" to the console
  Logger.log("Hello, world!");
}
```

This is a simple function named `helloWorld` that logs the string "Hello, world!" to the Google Apps Script logging console.

Here's what's happening in this example:

The `function` keyword declares that this is a function.

The `helloWorld` function name follows the function keyword.

The code inside the curly braces `{}` is the body of the function.

The `Logger.log` statement logs the message "Hello, world!" to the console.

You can run this script by selecting the code and clicking the "Run" button in the Google Apps Script editor, or by pressing `Ctrl + Enter` (`Cmd + Enter` on a Mac). When you run this script, the message "Hello, world!" will appear in the logging console.

This is just a simple example, but Google Apps Script provides a wide range of functionality that you can use to automate tasks, manipulate data, and interact with other Google Workspace services. With a little bit of code, you can streamline your work and save yourself a lot of time.

```
function hello(){  
  const message = 'Laurence Svekis';  
  Logger.log(message);  
}
```

```
for(let i=0;i<20;i++){
  Logger.log(i);
}
}
```

Execution log

5:25:44 PM	Notice	Execution started
5:25:44 PM	Info	Laurence Svekis
5:25:44 PM	Info	0.0
5:25:44 PM	Info	1.0
5:25:44 PM	Info	2.0
5:25:44 PM	Info	3.0

Adding numbers and showing an alert

Sheets Add Numbers UI Alert.

Google Apps Script that adds up two numbers and displays the result in a dialog box:

```
function addNumbers() {
  var num1 = 5;
  var num2 = 3;
  var result = num1 + num2;
  SpreadsheetApp.getUi().alert("The result is: " +
result);
}
```

Laurence Svekis <https://basescripts.com/>

```
}
```

Explanation:

The function `addNumbers` is defined.

Two variables `num1` and `num2` are defined and assigned values of 5 and 3 respectively.

The result of `num1 + num2` is calculated and stored in the variable `result`.

The `SpreadsheetApp.getUi().alert` method is used to display a dialog box with the text "The result is: 8", which is the value of the `result` variable.

This script can be run in a Google Spreadsheet by opening the script editor (under the "Tools" menu), copying and pasting the code into the editor, and then clicking the "Run" button

```
function showAl(){
  const num1 = 100;
  const num2 = 144;
  const result = num1 + num2;
  const output = `The result of ${num1} + ${num2} =
  ${result}`;
  SpreadsheetApp.getUi().alert(output);
}
```

Read Data from from Sheet

<https://youtu.be/FLY0pYMzl-o>

Google Apps Script that reads data from a Google Sheet, performs calculations on the data, and writes the results back to the sheet:

```
function calculateAverages() {  
  var sheet = SpreadsheetApp.getActiveSheet();  
  var data = sheet.getDataRange().getValues();  
  
  var total = 0;  
  for (var i = 0; i < data.length; i++) {  
    total += data[i][0];  
  }  
  var average = total / data.length;  
  
  sheet.getRange(data.length + 1, 1).setValue(average);  
}
```

Explanation:

The function `calculateAverages` is defined.

The sheet variable is set to the active sheet in the current spreadsheet using the SpreadsheetApp.getActiveSheet method.

The data variable is set to the values of all cells in the active sheet using the sheet.getDataRange().getValues method.

A for loop is used to sum up the values in the first column of the data array. The total variable is used to keep track of the sum.

The average value is calculated by dividing the total by the number of rows in the data (data.length).

The average value is written to the next empty row in the first column of the sheet using the sheet.getRange(data.length + 1, 1).setValue method.

This script can be run in a Google Spreadsheet by opening the script editor (under the "Tools" menu), copying and pasting the code into the editor, and then clicking the "Run" button. It will read the data in the sheet, perform the calculation, and write the result to the next empty row in column A.

Get sheet data - apply changes and set value in sheet data

	A	B	C
1	Name	hours	days
2	Laurence	100	12
3	Laura	50	6
4	John	1140	142
5	Laurence	50	6
6	Laura	350	43
7	John	33	4

```
function sheetData2(){
  const sheet =
  SpreadsheetApp.openById(ID).getSheetByName('data');
  const data = sheet.getDataRange().getValues();
  const headings = data[0];
  const results = data.slice(1);
  results.forEach((row,index) => {
    const days = (Math.floor(parseInt(row[1])/8));
    sheet.getRange(index+2,3).setValue(days);
  })
  //Logger.log(results);
}
```

Send email from Sheet

<https://youtu.be/3cd2Wj3yODk>

Google Apps Script that sends an email based on the contents of a Google Sheet:

```
function sendEmails() {  
    var sheet = SpreadsheetApp.getActiveSheet();  
    var data = sheet.getDataRange().getValues();  
  
    for (var i = 1; i < data.length; i++) {  
        var emailAddress = data[i][0];  
        var message = data[i][1];  
        var subject = "Important Message";  
  
        MailApp.sendEmail(emailAddress, subject, message);  
    }  
}
```

Use Sheet data for custom emails out

	A	B	C
1	Name	ID	Email
2	Laurence	100	gappscourses+1@gmail.com
3	Laura	50	gappscourses+2@gmail.com
4	John	1140	gappscourses+3@gmail.com
5	Laurence	50	gappscourses+4@gmail.com
6	Laura	350	gappscourses+5@gmail.com
7	John	33	gappscourses+6@gmail.com

```
function senderEmail(){
  const sheet = SpreadsheetApp
    .openById(ID)
    .getSheetByName('Users');
  const data = sheet.getDataRange().getValues();
  const users = data.slice(1);
  Logger.log(users);
  users.forEach((user, index)=>{
    const userName = user[0];
    const email = user[2];
    const id = user[1];
    const message = `Hello ${userName}, your id is
    ${id}`;
    MailApp.sendEmail(email, 'Welcome', message);
  })
}
```

<input type="checkbox"/>	☆	me	Welcome - Hello Laurence, your id is 100
<input type="checkbox"/>	☆	me	Welcome - Hello John, your id is 1140
<input type="checkbox"/>	☆	me	Welcome - Hello Laura, your id is 350
<input type="checkbox"/>	☆	me	Welcome - Hello Laurence, your id is 50
<input type="checkbox"/>	☆	me	Welcome - Hello Laura, your id is 50
<input type="checkbox"/>	☆	me	Welcome - Hello John, your id is 33

Explanation:

The function `sendEmails` is defined.

The sheet variable is set to the active sheet in the current spreadsheet using the `SpreadsheetApp.getActiveSheet` method.

The data variable is set to the values of all cells in the active sheet using the `sheet.getDataRange().getValues` method.

A for loop is used to iterate through the rows in the data array, starting from the second row (the first row is assumed to contain headers).

For each row, the email address is stored in the `emailAddress` variable, the message text is stored in the `message` variable, and the subject of the email is set to "Important Message".

The `mailApp.sendEmail` method is used to send an email to the address stored in `emailAddress`, with the subject and message stored in `subject` and `message` respectively.

This script can be run in a Google Spreadsheet by opening the script editor (under the "Tools" menu), copying and pasting the code into the editor, and then clicking the "Run" button. It will read the data in the sheet, send an email to each email address specified in column A, with the message specified in column B.

Send Emails to recipients from Sheet data

Google Apps Script that sends an email to a list of recipients based on data in a Google Sheet:

```
function sendEmails() {  
    var sheet = SpreadsheetApp.getActiveSheet();  
    var data = sheet.getDataRange().getValues();  
  
    for (var i = 1; i < data.length; i++) {  
        var email = data[i][0];  
        var subject = data[i][1];  
        var message = data[i][2];
```

```
    MailApp.sendEmail(email, subject, message);  
  }  
}
```

Explanation:

The function sendEmails is defined.

The sheet variable is set to the active sheet in the current spreadsheet using the SpreadsheetApp.getActiveSheet method.

The data variable is set to the values of all cells in the active sheet using the sheet.getDataRange().getValues method.

A for loop is used to iterate through the rows in the data array, starting from the second row (the first row is assumed to contain headers).

For each row, the email address, subject, and message are stored in the email, subject, and message variables respectively.

An email is sent to the recipient specified by email using the MailApp.sendEmail method, with the subject and message specified by subject and message respectively.

Send emails from User list in Sheets

Google Apps Script that sends an email to a list of recipients from a Google Sheet:

Laurence Svekis <https://basescripts.com/>

```

function sendEmails() {
    var sheet = SpreadsheetApp.getActiveSheet();
    var data = sheet.getDataRange().getValues();
    var subject = "Important Update";
    var message = "Hello,\n\nThis is an important update.
Please read carefully.\n\nBest regards,\nYour Name";

    for (var i = 1; i < data.length; i++) {
        var email = data[i][0];
        MailApp.sendEmail(email, subject, message);
    }
}

```

Explanation:

The function sendEmails is defined.

The sheet variable is set to the active sheet in the current spreadsheet using the SpreadsheetApp.getActiveSheet method.

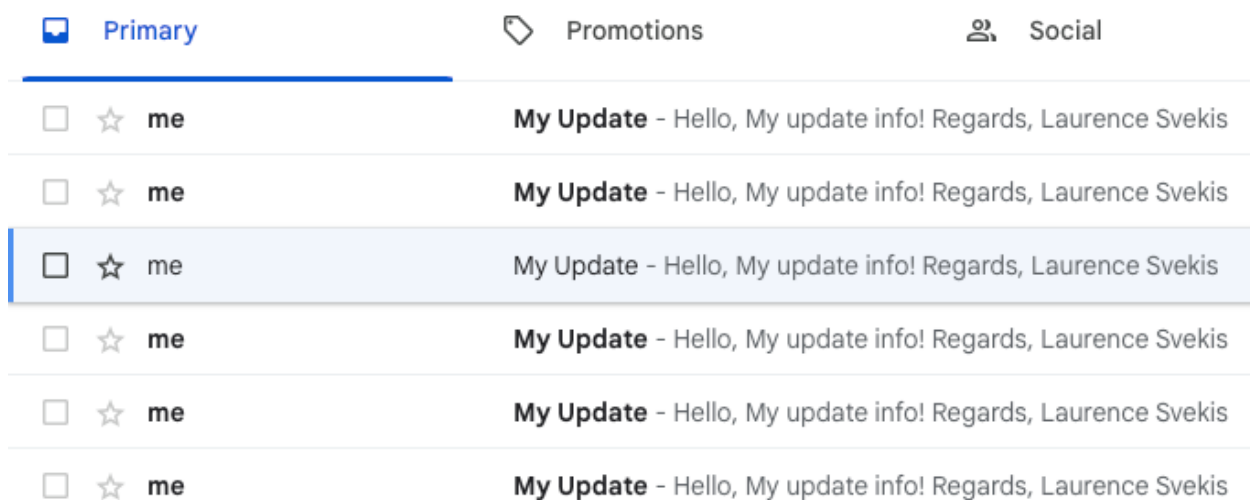

The data variable is set to the values of all cells in the active sheet using the sheet.getDataRange().getValues method.

The subject and message variables are set to the subject and message of the email respectively.

A for loop is used to iterate through the rows in the data array, starting from the second row (the first row is assumed to contain headers).

For each row, the email address is stored in the email variable. An email is sent to the recipient using the MailApp.sendEmail method, with the recipient's email address, subject, and message specified by email, subject, and message respectively.

Sending an email to all users from the spreadsheet data

```
function emailOut(){
  const sheet = SpreadsheetApp.getActiveSheet();
  const data = sheet.getDataRange().getValues();
  Logger.log(data);
  const subject = 'My Update';
  const message = 'Hello, \n\nMy update
info!\n\nRegards,\nLaurence Svekis';
  for(let i=1;i<data.length;i++){
    const email = (data[i][2]);
```

```
    MailApp.sendEmail(email,subject,message);  
  }  
}
```

Apps Script on Sheets examples

<https://youtu.be/K-bPqKBKRtk>

Google Apps Script that performs various operations on a Google Sheet, including formatting cells, calculating values, and creating charts:

```
function formatSheet() {  
  var sheet = SpreadsheetApp.getActiveSheet();  
  var data = sheet.getDataRange().getValues();  
  
  // Format the header row in bold  
  var headerRange = sheet.getRange(1, 1, 1,  
data[0].length);  
  headerRange.setFontWeight("bold");  
  
  // Add borders to all cells  
  var borderRange = sheet.getRange(1, 1, data.length,  
data[0].length);
```

Laurence Svekis <https://basescripts.com/>

```
borderRange.setBorder(true, true, true, true, null,
null);
```

```
// Calculate the sum of the values in column 1
```

```
var sum = 0;
```

```
for (var i = 1; i < data.length; i++) {
```

```
    sum += data[i][0];
```

```
}
```

```
// Write the sum to the bottom of column 1
```

```
sheet.getRange(data.length + 1, 1).setValue(sum);
```

```
// Create a chart to visualize the data
```

```
var chart = sheet.newChart()
```

```
    .setChartType(Charts.ChartType.BAR)
```

```
    .addRange(sheet.getRange(1, 1, data.length, 1))
```

```
    .setOption('title', 'Column 1 Data')
```

```
    .setOption('width', 400)
```

```
    .setOption('height', 300)
```

```
    .setPosition(5,6,0,0)
```

```
    .build();
```

```
sheet.insertChart(chart);
```

```
}
```

Explanation:

The function `formatSheet` is defined.

The `sheet` variable is set to the active sheet in the current spreadsheet using the `SpreadsheetApp.getActiveSheet` method.

The `data` variable is set to the values of all cells in the active sheet using the `sheet.getDataRange().getValues` method.

The header row is formatted in bold by getting the range of cells in the first row and using the `setFontWeight` method to set the font weight to "bold".

Borders are added to all cells by getting the range of all cells and using the `setBorder` method to set all borders to true.

The sum of the values in column 1 is calculated using a for loop and stored in the `sum` variable.

The sum is written to the bottom of column 1 using the `sheet.getRange(data.length + 1, 1).setValue` method.

A bar chart is created to visualize the data in column 1 using the Charts service and the `sheet.newChart` method. The chart options, such as the title and dimensions, are set using the `setOption` method. The chart is inserted into the sheet using the `sheet.insertChart` method.

This script can be run in a Google Spreadsheet by opening the script editor (under the "Tools" menu), copying and pasting the code into the editor, and then clicking the "Run" button. It will

format the cells in the sheet, calculate the sum of the values in column 1, and insert a chart to visualize the data.

Using Sheet data create a chart update styling

```
function formatSheetData(){
  const sheet =
SpreadsheetApp.getActiveSpreadsheet().getSheets()[1];
  sheet.getRange(1,4,1,1).setValue('Total');
  const data = sheet.getDataRange().getValues();
  const headerRange =
sheet.getRange(1,1,1,data[0].length);
  headerRange.setFontWeight('bold');
  headerRange.setFontSize(20);
  const borderRange =
sheet.getRange(1,1,data.length,data[0].length);

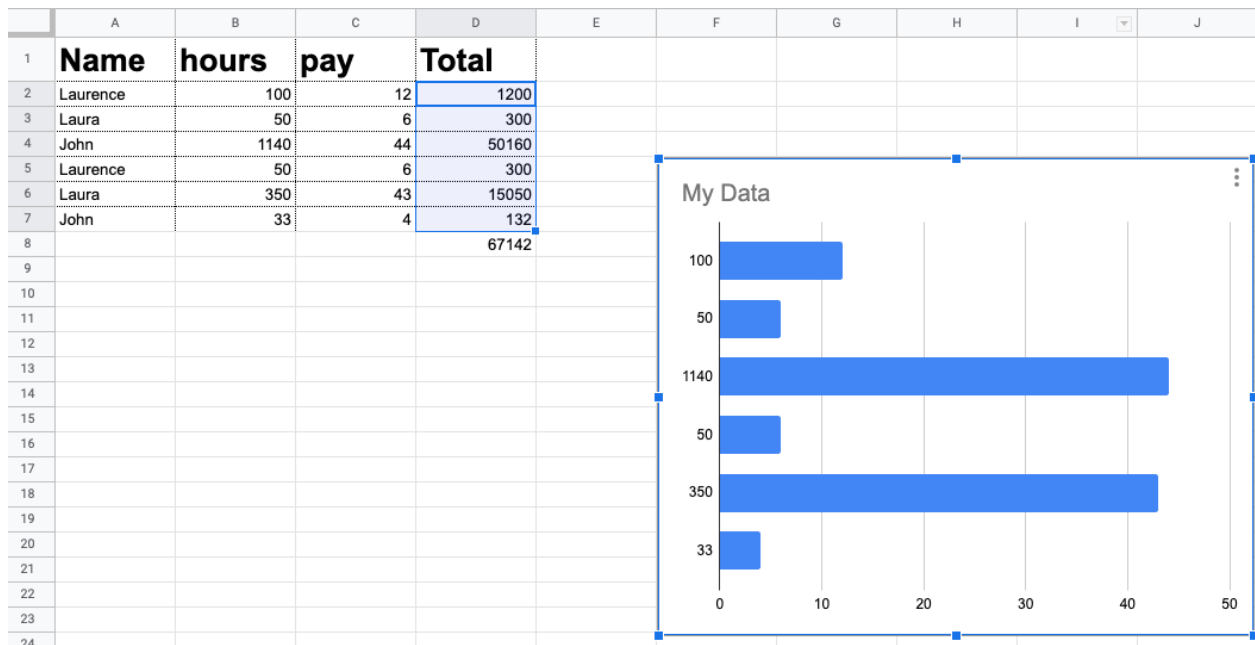

borderRange.setBorder(true,false,false,true,true,true,'
black',SpreadsheetApp.BorderStyle.DOTTED);
  let total = 0;
  for(let i=1;i<data.length;i++){
```

```

    let sum = parseInt(data[i][1]) *
parseInt(data[i][2]);
    sheet.getRange(i+1,4,1,1).setValue(sum);
    Logger.log(sum);
    total += sum;
}
sheet.getRange(data.length+1,4,1,1).setValue(total);
const myChart = sheet.newChart()
    .setChartType(Charts.ChartType.BAR)
    .addRange(sheet.getRange('B2:C7'))
    .setOption('title','My Data')
    .setOption('width',500)
    .setOption('height',400)
    .setPosition(5,6,0,0)
    .build();
sheet.insertChart(myChart)

Logger.log(total);
}

```

Apps Script Create Calendar entries from Sheet data

<https://youtu.be/k0crpbB1qcM>

Google Apps Script that automatically creates and updates a Google Calendar event based on data in a Google Sheet:

```
function createCalendarEvent() {
  var sheet = SpreadsheetApp.getActiveSheet();
  var data = sheet.getDataRange().getValues();

  for (var i = 1; i < data.length; i++) {
    var startTime = data[i][0];
```

```

    var endTime = data[i][1];
    var eventName = data[i][2];
    var calendar =
CalendarApp.getCalendarById(data[i][3]);

    var event = calendar.createEvent(eventName,
startTime, endTime);
    }
}

function updateCalendarEvent() {
    var sheet = SpreadsheetApp.getActiveSheet();
    var data = sheet.getDataRange().getValues();

    for (var i = 1; i < data.length; i++) {
        var eventId = data[i][4];
        var event = CalendarApp.getEventById(eventId);

        var startTime = data[i][0];
        var endTime = data[i][1];
        var eventName = data[i][2];
        var calendar =
CalendarApp.getCalendarById(data[i][3]);

```

```
    event.setTitle(eventName);  
    event.setStartTime(startTime);  
    event.setEndTime(endTime);  
    event.setCalendar(calendar);  
  }  
}
```

Explanation:

The function `createCalendarEvent` is defined.

The `sheet` variable is set to the active sheet in the current spreadsheet using the `SpreadsheetApp.getActiveSheet` method.

The `data` variable is set to the values of all cells in the active sheet using the `sheet.getDataRange().getValues` method.

A for loop is used to iterate through the rows in the `data` array, starting from the second row (the first row is assumed to contain headers).

For each row, the start time, end time, event name, and calendar ID are stored in the `startTime`, `endTime`, `eventName`, and `calendar` variables respectively.

A new event is created in the calendar specified by calendar using the calendar.createEvent method, with the start time, end time, and event name specified by startTime, endTime, and eventName respectively.

The function updateCalendarEvent is defined.

The sheet and data variables are set in the same way as in the createCalendarEvent function.

A for loop is used to iterate through the rows in the data array, starting from the second row.

For each row, the event ID is stored in the eventId variable, and the event is retrieved using the CalendarApp.getEventById method.

The start time, end time, event name, and calendar ID are stored in the startTime, endTime, eventName, and calendar variables respectively.

The event is updated using the setTitle, setStartTime, setEndTime, and setCalendar methods

Sheet data to create Calendar events

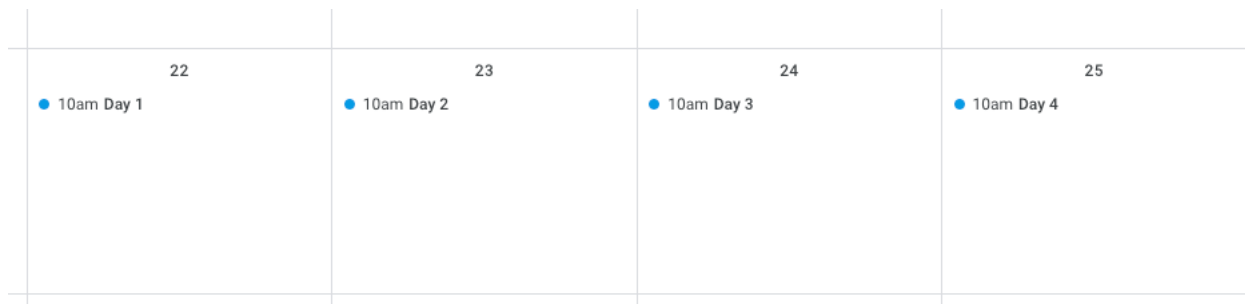

Event	Start	End	Location	Description
Day 1	3/22/2023 10:00:00	3/22/2023 12:00:00	online	Another Day starts 1
Day 2	3/23/2023 10:00:00	3/23/2023 12:00:00	online	Another Day starts 2
Day 3	3/24/2023 10:00:00	3/24/2023 12:00:00	online	Another Day starts 3
Day 4	3/25/2023 10:00:00	3/25/2023 12:00:00	online	Another Day starts 4
Day 5	3/26/2023 10:00:00	3/26/2023 12:00:00	online	Another Day starts 5

```
const ID = '132trziyLsk8qIk';
function makeEvents(){
  const sheet =
SpreadsheetApp.openById(ID).getSheetByName('Cal');
  const data = sheet.getDataRange().getValues();
  const events = data.slice(1);
  const headings = data[0];
  events.forEach((event, index)=>{
    const start = event[1];
    const nameEvent = event[0];
    const end = event[2];
    const loc = event[3];
```

```

const des = event[4];
const cal =CalendarApp.getDefaultCalendar();
const eve = cal.createEvent(nameEvent,start,end,{
  location:loc,
  description:des
});
Logger.log(cal);
})
}

```

Calendar Events into Sheet

```

function updateCal(){
  const cal =CalendarApp.getDefaultCalendar();
  const ss = SpreadsheetApp.openById(ID);
  const start = new Date();
  const end = new Date(start.getTime() +
(100*24*60*60*1000));
  const events = cal.getEvents(start,end);
  Logger.log(events);
}

```

Laurence Svekis <https://basescripts.com/>

```

const sheet = ss.insertSheet();

sheet.appendRow(['Name', 'Start', 'End', 'Location', 'ID'])
;
sheet.setName('New Event List');
events.forEach(event => {
  const arr =
[event.getTitle(), event.getStartTime(), event.getEndTime
()], event.getLocation(), event.getId());
  sheet.appendRow(arr);
})
}

```

Sheet data to populate Calendar

Google Apps Script that copies the data from a Google Sheet to a Google Calendar:

```

function copyToCalendar() {
  var sheet = SpreadsheetApp.getActiveSheet();
  var data = sheet.getDataRange().getValues();
  var calendar =
CalendarApp.getCalendarById("your_calendar_id");

```

```

for (var i = 1; i < data.length; i++) {
  var date = data[i][0];
  var eventName = data[i][1];
  var description = data[i][2];

  var start = new Date(date);
  var end = new Date(date);
  end.setHours(end.getHours() + 1);

  calendar.createEvent(eventName, start, end, { description:
description });
}
}

```

Explanation:

The function copyToCalendar is defined.

The sheet variable is set to the active sheet in the current spreadsheet using the SpreadsheetApp.getActiveSheet method.

The data variable is set to the values of all cells in the active sheet using the sheet.getDataRange().getValues method.

The calendar variable is set to the calendar with the specified ID using the CalendarApp.getCalendarById method. Replace "your_calendar_id" with the actual ID of your calendar.

A for loop is used to iterate through the rows in the data array, starting from the second row (the first row is assumed to contain headers).

For each row, the date, event name, and description are stored in the date, eventName, and description variables respectively.

The start variable is set to a new date object created from the date variable.

The end variable is set to a new date object created from the date variable, with the number of hours increased by 1.

A new event is created in the calendar using the calendar.createEvent method, with the event name, start and end times, and description specified by eventName, start, end, and description respectively.

Logs Email Attachments details

<https://youtu.be/JvvHPMsAGcM>

Google Apps Script that logs information about all attachments in a Gmail account:

```
function logAttachments() {  
    var threads = GmailApp.search("has:attachment");  
  
    for (var i = 0; i < threads.length; i++) {  
        var messages = threads[i].getMessages();
```

Laurence Svekis <https://basescripts.com/>

```

for (var j = 0; j < messages.length; j++) {
    var attachments = messages[j].getAttachments();

    for (var k = 0; k < attachments.length; k++) {
        var attachment = attachments[k];
        var fileName = attachment.getName();
        var size = attachment.getSize();

        Logger.log("Attachment: " + fileName + " -
Size: " + size + " bytes");
    }
}
}
}
}

```

Explanation:

The function logAttachments is defined.

The threads variable is set to an array of all threads in the Gmail account that have attachments, using the GmailApp.search method with the query "has:attachment".

A for loop is used to iterate through the threads in the threads array.

For each thread, the messages variable is set to an array of all messages in the thread using the threads[i].getMessages method.

Another for loop is used to iterate through the messages in the messages array.

For each message, the attachments variable is set to an array of all attachments in the message using the messages[j].getAttachments method.

Another for loop is used to iterate through the attachments in the attachments array.

For each attachment, the fileName and size variables are set to the name and size of the attachment respectively, using the attachment.getName and attachment.getSize methods.

The information about the attachment is logged to the Google Apps Script log using the Logger.log method.

Get Gmail Attachments Log into Sheet

```
function getAtt(){  
  const id = '132trvLa8IvLsk8qIk';
```

```

const threads = GmailApp.search('has:attachment');
const ss = SpreadsheetApp.openById(id);
const sheet = ss.insertSheet();
sheet.setName('Attachments');
threads.forEach(thread =>{
  const messages = thread.getMessages();
  messages.forEach(message => {
    const attments = message.getAttachments();
    attments.forEach(attachment =>{
      Logger.log(attachment.getName());
      const arr =
[attachment.getName(),attachment.getSize(),attachment.g
etContentType()];
      sheet.appendRow(arr);
    })
  })
})
}

```

Create folder in drive from Sheet Data

<https://youtu.be/CSmch7KNRnw>

Google Apps Script that creates a new folder in Google Drive for each row in a Google Sheet and stores a PDF file with the contents of a specific column in that folder:

```
function createFoldersAndFiles() {  
  var sheet = SpreadsheetApp.getActiveSheet();  
  var data = sheet.getDataRange().getValues();  
  var parentFolder =  
  DriveApp.getFolderById("your_parent_folder_id");  
  
  for (var i = 1; i < data.length; i++) {  
    var folderName = data[i][0];  
    var contents = data[i][1];  
    var folder = parentFolder.createFolder(folderName);  
  
    var file = folder.createFile("contents.pdf", contents,  
    MIMEType.PDF);  
  }  
}
```

Explanation:

The function createFoldersAndFiles is defined.

The sheet variable is set to the active sheet in the current spreadsheet using the SpreadsheetApp.getActiveSheet method. The data variable is set to the values of all cells in the active sheet using the sheet.getDataRange().getValues method. The parentFolder variable is set to the folder with the specified ID using the DriveApp.getFolderById method. Replace "your_parent_folder_id" with the actual ID of your parent folder. A for loop is used to iterate through the rows in the data array, starting from the second row (the first row is assumed to contain headers). For each row, the folder name and contents are stored in the folderName and contents variables respectively. A new folder is created in the parent folder using the parentFolder.createFolder method and the folder name is specified by folderName. A new file with the contents of the contents variable is created in the new folder using the folder.createFile method, with the file name "contents.pdf" and MIME type PDF specified by "contents.pdf" and MimeType.PDF respectively.
